

# Discussion & conclusion

## Information-theoretic constraints on general bigram distinctiveness

- Generalizable information-theoretic conditioning on variation:
  - When a bigram is more informative given the preceding context, the target phone2 maintains **higher distinctiveness/is more resilient to variation**.
  - Such effects are weaker in articulation (for the AE datasets).

# Discussion & conclusion

## The role of flexibility

- Flexibility allows for more contextually similar articulatory synergies & acoustically more distinctive speech targets at the same time.
  - Satisfies both **articulatory efficiency** & **perceptual recoverability**.
