

Methods

Statistical analysis–Limited imaging

- Compared to MRI, ultrasound & EMA are limited in terms of the articulators that could be imaged:
 - Ultrasound: excluded /ɹ/, /m, n, ŋ/, /ɑ, ɒ, ɐ, æ, a, aʊ, aɪ, ə/ (56.37%)
 - EMA: excluded /m, n, ŋ/ (19.53%)

Interim summary

Questions probed in this study

- Do we see surprisal effects overall across acoustics & articulation?
- Does speech flexibility (i.e., degree of freedom between articulatory synergies & speech target) enhance surprisal effects in acoustics & decrease surprisal effects in articulation?
